AEIOU Summary Canvas

Domain: Agriculture | Group: Agri_Developers | Date: Oct 2025 | Version: 1.0

Project: Agriculture — AgroVerify Input Verification System
Team: Agri_Developers

■ Environment

General Impressions

- Rural Indian village — dusty agri-input shop, open-air mandi, small farm plots of 1-2 acres
- Farmers operate in low-connectivity zones; mobile data is 2G or absent; electricity unreliable

Physical Setting

- Shop: shelves of seed packets, fertilizer bags, pesticide bottles with no visible certification marks
- Farm: hand-tilled soil, manual irrigation channels, produce sorted in open jute sacks

Atmosphere

- Farmers rely entirely on dealer word-of-mouth — no independent verification mechanism exists
- High trust in local dealers despite widespread awareness of fake inputs in the market

Special Notes

- Counterfeit products look identical to genuine ones — packaging is professionally replicated
- Seasonal urgency means farmers buy without verification — planting windows cannot be delayed

■ Interactions

Who Interacts With Whom

- Farmer ↔ Agri-input dealer (most critical interaction — no verification at point of sale)
- Farmer ↔ ASHA/Krishi Vigyan Kendra worker (occasional, for scheme info — not for inputs)
- Farmer ↔ Mandi agent (price negotiation — farmer always has less information)

How Interactions Happen

- Verbal and trust-based — no digital record, no receipt, no product verification
- Dealer recommends brand; farmer buys based on price and familiarity, not certification

Scene of Interaction

- Input shop 2 weeks before sowing season — farmer has cash in hand, no time to verify
- Urgency and limited options mean farmer cannot walk away even when suspicious

Special Notes

- Farmer has no tool, no database access, and no authority figure to call in the moment

■ Objects

Key Objects Involved

- Seed packets — often with QR code that links to no database or to a broken URL
- Pesticide bottles — no standardised label format; expiry dates sometimes absent
- Fertilizer bags — bulk, hard to trace origin; often refilled with cheaper substitutes

Inventory

- Farmer smartphone (if any): basic Android, 2-4 GB RAM, poor camera
- Dealer POS: none — all transactions verbal or handwritten in register
- SATHI portal: exists at government level but no farmer interface built

Features & Special Notes

- AgroVerify adds: QR scanner on app, SMS lookup for keypad phones, offline cache
- Batch number printed on packet becomes the verification key — zero new packaging needed
- Verification result in Gujarati/Hindi/Marathi — no literacy barrier

■ Activities

Primary Activities Observed

- Pre-sowing: farmer visits 1-3 shops, compares prices — verification never happens
- Sowing: inputs used immediately — no window to check quality until crop fails
- Post-failure: farmer realises inputs were fake 3-4 weeks later after crop fails to germinate

With AgroVerify — Changed Activity Flow

- Step 1: Farmer picks up packet at shop
- Step 2: Scans QR code on AgroVerify app OR dials toll-free number, enters batch code
- Step 3: App returns: GENUINE / SUSPECT with manufacturer name, expiry, certification date
- Step 4: If suspect — farmer does not buy; app logs incident for agriculture department

Sketch of Activity

- Phone → QR Scan → SATHI API → Verified ✓ | Fake ✗ → Farmer Decision → Logs to Dashboard

Special Notes

- Entire verification takes under 15 seconds — fits within the normal purchase interaction
- No additional steps required from dealer — does not create friction in the system

■■■ Users

Who Is Present — Roles & Responsibilities

- Small/marginal farmer (primary user): under 2 acres, seasonal crop, limited cash buffer
- Agri-input dealer: sells seeds, fertilizers, pesticides; often unaware product is fake
- Agriculture extension officer (KVK): awareness and training role — periodic village visits
- CSC operator: Common Service Centre — digital access point in many villages

Scene of User in Context

- Farmer: male or female, 35-60 yrs, primary school education, feature phone or basic Android
- Has ~■5,000-20,000 in hand for inputs; losing this to fake seeds = financial crisis
- Relies on seasonal crop for entire year's income — one bad batch = one lost year

Elements, Features & Special Notes

- Most critical user need: INSTANT, SIMPLE, LOCAL LANGUAGE verification at point of purchase
- Secondary users: agriculture officers (get real-time fake-input location data for enforcement)
- Tertiary: government (SATHI team gets farmer-level scan data to identify fraud hotspots)
- Design constraint: must work on ■2,000 keypad phones — cannot require smartphone or internet
